Introduction

This text is a curated not comprehensible mangle of topics mainly about LLMs (Large Language Models) based on the Transformer architecture. There is also an overview of ML Algorithms as they are still the best option for their designated purposes. If a ML Algorithm can do the job, don't use a deep neural network. Not every problem is a nail! Actually LLMs are plain math, some linear algebra and stochastics mainly. To get a deeper insight into the details of the Transformer architecture, it is necessary to hit the math behind. This text tries to explain the principles without math as far as possible. If you skip the math part, it should be possible to grasp the meaning of the principles anyway. The harder (depends) part of each section is explicitly marked. As stated, at that point you should have got the meaning of the section.

Getting ollama up and running

Installation process is shown for the Mac with homebrew. This should not be much more difficult on other OS. It's assumed that you have homebrew on your Mac and you are able to install packages with it.

Install ollama with homebrew

```
brew install ollama
ollama --version
#get rid of it
brew uninstall ollama
```

Run ollama as a service

```
brew services start ollama
#you can also stop it that way
brew services stop ollama
```

If you don't want to run it as a service, just start it manually

```
ollama serve
#pull the model
#run the model
ollama pull mistral
```

Pull a model for local usage (hopefully open source dude)

Out of sovereignty, ecological and last but not least economical reasons, it's recommended to use a local model with at least free weights. Recommendation would be Mistral:latest because of the aforementioned reasons. As ollama supports the ChatGPT API, it is easy to change to a larger model in the cloud. The limiting factor for local LLMs is mostly the hardware at hand. Anyway, for most agentic scenarios and for demonstration purposes fits Mistral quit well. Let's pull the model:

```
ollama pull mistral
```

To see the list of models at hand:

```
ollama list
```

$$\alpha = \frac{\mathbf{K} \mathbf{Q}}{\sqrt{S}}$$

This is text with math: $E = m \cdot c^2$
